#### 1. Introduction

#### 2. Model

#### 3. Algorithms

- Exact Algorithms
- Heuristics

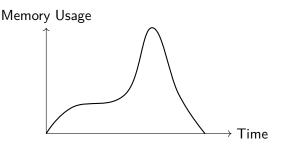

#### 4. Experiments

- Heuristics
- Comparison with Peak
- Parallel Execution

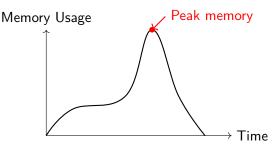

#### 5. Conclusion

- Problem: Scheduling task graphs to minimize memory consumption rather than execution speed.
- Context: High-performance computing, especially for applications with large memory footprints (e.g., machine learning).
- Objective: Reduce memory writes to external storage by minimizing memory usage during execution.

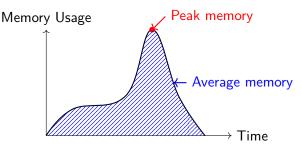

- Previous approaches target the minimization of the peak memory
- It may not be effective in shared memory environments
- We focus on reducing average memory consumption to improve overall performance

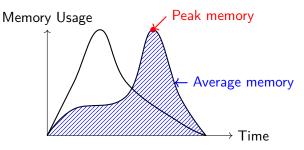

- Previous approaches target the minimization of the peak memory
- It may not be effective in shared memory environments
- We focus on reducing average memory consumption to improve overall performance

# 2 Memory models

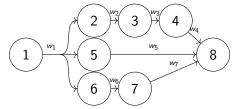

Figure: Pumpkin graph in the *multiple data* model

Figure: Pumpkin in the *single data* model

- Task Graphs: Represented by Directed Acyclic Graphs (DAGs).
- Vertices (V): Tasks.
- **Edges (E):** Data dependencies between tasks.
- Goal: Execute tasks to minimize memory consumption while respecting data dependencies and execution times.

#### Model - multiple data

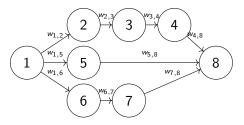

Figure: Pumpkin graph in the *multiple data* model

- Each edge (u, v) has an associated data of weight w<sub>u,v</sub>
- The data stays in memory until all v has started its execution
- Equivalent to the Weighted Linear Arrangement problem

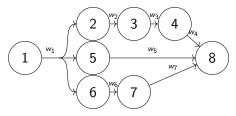

#### Definition (Weighted Linear Arrangement)

Given a valid schedule  $\phi$  for a DAG G, we define the weighted linear arrangement cost of  $\phi$  by:

$$WLA_G(\phi) = \sum_{(u,v)\in E} w_{u,v}(\phi(v) - \phi(u))$$

### Model - single data

- Each vertex v has an associated outgoing data of weight wv
- The data stays in memory until all childs of v have started being executed

Equivalent to the Weighted Sum Cut problem
Figure: Pumpkin in the single data model

#### Definition (Weighted Sum Cut)

Given a valid schedule  $\phi$  for a DAG *G*, we define the weighted sumcut of  $\phi$  by:

$$WSC_G(\phi) = \sum_{u \in V} w_u \max_{v \in V^+(u)} (\phi(v) - \phi(u))$$

э

We want to split the graph in half, to reuse algorithms on in-trees and out-trees

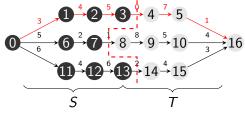

Figure: Min-cut (S, T) of a graph G

We want to split the graph in half, to reuse algorithms on in-trees and out-trees

Reducing the cost along chain 1

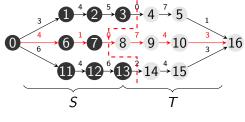

Figure: Min-cut (S, T) of a graph G

We want to split the graph in half, to reuse algorithms on in-trees and out-trees

Reducing the cost along chain 2

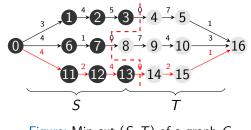

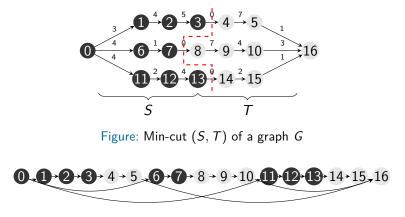

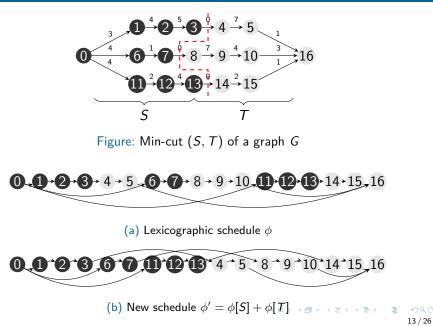

Figure: Min-cut (S, T) of a graph G

We want to split the graph in half, to reuse algorithms on in-trees and out-trees

Reducing the cost along chain 3

(a) Lexicographic schedule  $\phi$ 

- Finding the min cut:  $\mathcal{O}(n)$
- ► Solving Linear Arrangement on in-tree and out-tree: O(n log(n))
- ▶ Gives an  $O(n \log(n))$  algorithm

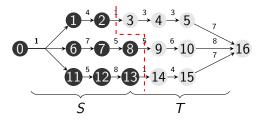

Figure: Cut (S, T) of a graph G

We can't split at the min-cut like before

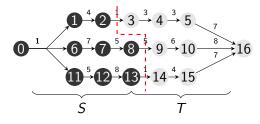

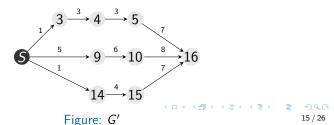

Figure: Cut (S, T) of a graph G

- We can't split at the min-cut like before
- Transform our graph into another pumpkin in the multiple data model

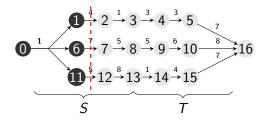

Figure: Cut (S, T) of a graph G

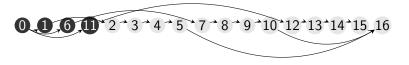

Figure: Schedule transformation with a cut

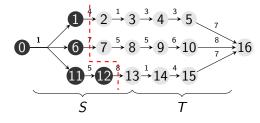

Figure: Cut (S, T) of a graph G

Figure: Schedule transformation with a cut

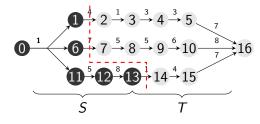

Figure: Cut (S, T) of a graph G

Figure: Schedule transformation with a cut

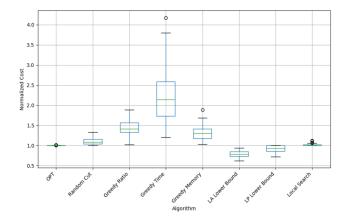

- $\mathcal{O}(n^k)$  cuts
- Solving Linear Arrangement on in-tree and pumpkin:  $O(n \log(n))$
- Gives an  $\mathcal{O}(n^k n \log(n))$  algorithm

We look for heuristics, as we are competing against an  $O(n \log(n))$  algorithm.

- Greedy algorithms (greedy memory, greedy time)
- Random cut
- Local search

- C++ implementation of all the algorithms using the Boost Graph Library
- TaGaDa tool for graph generation
- Some other graphs from real world applications (trees)
- Compared with the state of the art algorithm for reducing the Peak memory usage

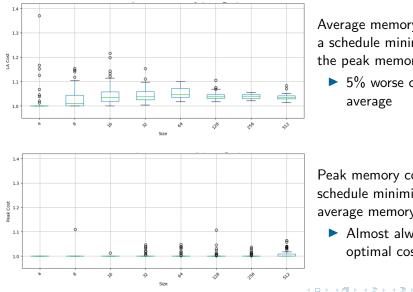

### Experiments - Heuristics for WSC on pumpkins

Comparison of heuristics for WSC (single data) on random pumpkins

Local search is on average within 5% of the optimal cost

### Experiments - Comparing average and peak

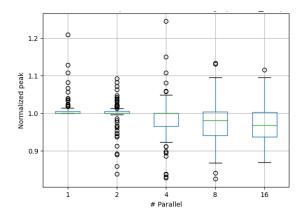

Average memory cost of a schedule minimizing the peak memory

▶ 5% worse cost on average

Peak memory cost of a schedule minimizing the average memory

Almost always the optimal cost

#### **Experiments - Parallel Execution**

- Multiple task graphs in parallel
- Minimizing the peak memory for each graph compared to minimizing the average memory for each graph
- The overall peak is up to 5% lower by using average rather than peak!

- Novel approach for scheduling task graphs to reduce average memory consumption.
- New exact algorithms and heuristics.
- Improved performance in parallel processing setups compared to focusing on the peak.

Thank you for your attention! Any questions?
